Network Construction and Network Features Generation.
We generate a second set of product-level features using review and product imag es. First, we use a pretrained deep convolutional neural network (12) for all im ages (both product and review) to extract the features as shown in SI Appendix, Fig. S1. We then calculate the angular similarity of all the images belonging to the same product, using the cosine distance between the vector representation o f each image. Cosine distance is particularly effective for high-dimensional dat a (13). We calculate three sets of features that summarize the degree of image s imilarity between all product reviews (controlling for multiple images belonging) Tj T* BT /F1

nd the review images, and the similarity among all pairs of review images. For e ach set of features, we calculate the minimum, maximum, average, and SD of the p air-wise similarities within a product.
share photo Share of reviews with review photo
This analysis shows that just two clusters (that contain only 3.4% of products) contain about 70% of the products identified as fake review buyers. In addition, within one of these clusters, a substantial majority of products are identified as buying fake reviews (83%). In SI Appendix, Table S4, we report the mean of t he feature values in each cluster. The two clusters that contain the majority of fake-review buyers are highly distinctive, and only in terms of their network f eatures. This suggests that a platform could use unsupervised methods to identif y these tightly connected clusters of products without any ground truth data and use this information to identify likely fake review buyers.
